4) f string method :

```
name = "suma"
age = 27
print(f"my name is {name} and my age is {age}")
```

output :

my name is suma and my age is 27.

15/10/26

comments :

They are the part of programming but they never part of execution. They used to understand the flow of programming or some critical logics.

Types of comments :

1) single line comment

```
# it's single line comment.
```

2) multiline comment

```
''' its multiple comment '''
""" its multiple comment """
```

keywords :

They are the predifined words to perform a specific task.

ex: if, for, else, break .....

These keywords are not used as identifiers. (variables, function name ....)

* import keyword

```
print(keyword.kwlist)
```

['false', 'none', 'True', 'and', 'as', 'assert', 'async', 'await', 'Break', 'class', 'def', 'del', 'elif', 'if', 'else']

These are the keywords are not using the variable of starting point

variables :-

They are place holders which the holds any kind of value and they Represented by variable names.

Rules for variable declaration :-

1) variable can be upper case or lower case.
2) It can be single alphbet or string or alphnumeric
3) we can use dual words as single variable but they should separated by - (underscore).
4) They cant be start with numbers.
5) They cant use any special char apart from _
6) we cant bseperate them by space

valid variable declaration

1) A = 6
2) a = 5
3) place = "Bengaluru"
4) stu_name = "Rama"
5) num1 = 20
6) num2 = 50
7) _stu_id_ = 2931

Invalid variable declarations

1) stu phonenum = 7589698502
2) emp@name$comp = "Sanjana"
3) 1num = 100

write program for addition of 2 nums

ex:- the sum of 5 and 2 is 7

```
a = int(input("enter a value:"))
b = int(input("enter a value:"))
print(f"The sum of {a} and {b} is {a+b}")
```

write a program to calculate area of circle and area of triangle

Area of circle :-

```
r = float (input ("enter a value:"))
aoc = 3.142 * r*r
print ("the Area of circle is :", aoc)
```

Area of Triangle

```
b = float (input ("enter a base of triangle"))
h = float (input ("enter a height of triangle"))
aot = (1/2) 0.5 * b*h
print ("the Area of triangle is :", aot)
print (f" the Area of triangle is {aot :.2f}")
```

16/10/26 :-

Read stu name, stu Id and three subjects marks for each 100 and display the student details.

```
sname = input ("enter your name :")
sid = input ("enter your student ID:")
s1 = int (input ("enter a subject1 marks :"))
s2 = int (input ("enter subject 2 marks :"))
s3 = int (input ("enter subject 3 marks :"))
total marks = s1 + s2 + s3
percentage = (tm/300) * 100 (or) tm/3
print (f" student name : {sname} \n student Id : {sid} \n
    subject1 : {s1} \n subject2 : {s2} \n subject 3 : {s3} \n
    total marks : {tm} \n percentage : {per} ")
```
